(Received 19 November 1996)

In this work we construct a correlated double continuum wave function for the three-body Schrödinger equation valid for large interparticle distances. Genuine three-body effects are considered by taking into account a nondiagonal part of the Hamiltonian written in generalized parabolic coordinates. A solution is found in terms of the confluent hypergeometric function of two variables $\Phi_2$, with similar structure to the first-order Faddeev approximation. The use of such a solution seems to introduce appropriately the interelectronic repulsion. [S1050-2947(97)06804-2]

I. INTRODUCTION

The three-body Coulomb continuum problem is of fundamental importance in atomic physics. There are several mechanisms leading to three unbounded particles in the final state, such as single ionization by electron impact, double photoionization, or double Compton. In all these cases we have to deal with two electrons in the continuum. Several approximate double continuum wave functions have been used to compute the correspondent cross sections. The most simple approximation consists of neglecting one of the interactions; namely, the electron-electron ($e-e$) repulsion. This leads to a solution expressed in terms of a product of two Coulomb waves, the so-called C2 approximation. It produces reasonable agreement with measured total cross section for Coulomb waves, the so-called C3 approximation. To some extent, this correlation can be neglected all mixed derivatives of the three-body Hamiltonian written in generalized parabolic coordinates [3]. This wave function is expressed in terms of a product of three Coulomb waves, the so-called C3 approximation [3–5]. Unlike the C2, the C3 approximation tends to the exact solution of the problem for large interparticle distances. However, this solution underestimates by orders of magnitude the threshold of total cross sections [6] because of an overestimation of the electron repulsion.

To avoid this defect it is necessary to find a wave function where the variables of the system are correlated so that, for certain configurations, the repulsion between the electrons becomes shielded by the presence of the nucleus. In recent years, new correlated wave functions have been developed. These solutions have the same structure as the C3 approximation, but with effective momenta [7] or charges [8] depending “slowly” on the coordinates. In order to determine to what extent this kind of approach introduces correlation, in Sec. II, we solve numerically a model Hamiltonian considering two electrons in the field of a nucleus for a particular configuration. We find that the use of effective momenta does not provide a fully satisfactory answer to the problem. In Sec. III, we look for a solution beyond the C3 approximation. We find a double continuum wave function in terms of the hypergeometric function of two variables $\Phi_2$, which is an exact solution for large interparticle distances. Finally in Sec. IV, we expose our main conclusions and outlook. Atomic units will be employed throughout this work.

II. THE THREE-BODY COULOMB EQUATION IN GENERALIZED PARABOLIC COORDINATES

Let us consider two electrons in the Coulomb field of a heavy nucleus whose mass is considered infinite. The sets of Jacobi coordinates are shown in Fig. 1. The nonrelativistic Hamiltonian of the three-body system is given by

$$\left( \nabla_1^2 + \nabla_2^2 + \frac{2Z_1}{r_1} + \frac{2Z_2}{r_2} + \frac{2Z_3}{r_3} - E \right) \Psi = 0,$$

where $Z_1 = Z_2 = Z$ is the nuclear charge, $Z_3 = -1/2$ represents the strength of the $e-e$ repulsion, and $E = k_1^2/2 + k_2^2/2$ is the total energy. It is convenient here to make two transformations. First, we remove the plane-wave asymptotic condition by writing

$$\bar{\Psi} = (2\pi)^{-3} \exp(ik_1 \cdot r_1 + ik_2 \cdot r_2) \Psi,$$

where $k_1$ ($k_2$) is the momentum of the electron “1” (“2”) with respect to the heavy nucleus, and $k_1 = (k_1 - k_2)/2$ is the

![FIG. 1. Set of Jacobi coordinates. When the nucleus mass tends to infinity, then $R_1 \rightarrow r_2$ and $R_2 \rightarrow r_1$.](image-url)
e-e relative momentum. Second, we follow the work of Klar [3] introducing the following generalized parabolic coordinates:

\[ \xi_j = r_j + r_j \hat{k}_j, \quad \eta_j = r_j - r_j \hat{k}_j, \quad j = 1,2,3. \]  

(3)

After significant algebra, one can find that Eq. (1) transforms into

\[ H\Psi = (H_{C3} + W_{C3})\Psi = 0, \]  

(4)

where \( H \) is the total Hamiltonian,

\[ H_{C3} = \sum_{j=1}^{3} \frac{1 + \delta_{j,3}}{\xi_j + \eta_j} (H_j^+ + H_j^+ + Z_j), \]  

(5)

\[ H_j^+ = \frac{\partial}{\partial \xi_j} \xi_j \frac{\partial}{\partial \xi_j} + ik_j \xi_j \frac{\partial}{\partial \xi_j}, \]  

(6)

\[ H_j^+ = \frac{\partial}{\partial \eta_j} \eta_j \frac{\partial}{\partial \eta_j} + ik_j \eta_j \frac{\partial}{\partial \eta_j}, \]  

(7)

\[ W_{C3} = \sum_{l=1}^{2} (-1)^{l+1} \left[ t_j^+ \cdot t_j^+ \frac{\partial^2}{\partial \xi_j \partial \xi_j} + t_j^+ \cdot t_j^+ \frac{\partial^2}{\partial \eta_j \partial \eta_j} \right. \]  

\[ \left. + t_j^0 \cdot t_j^0 \frac{\partial^2}{\partial \xi_j \partial \xi_j} + t_j^0 \cdot t_j^0 \frac{\partial^2}{\partial \eta_j \partial \eta_j} \right]. \]  

(8)

and

\[ t_j^+ = \hat{r}_j + \hat{k}_j, \quad j = 1,2,3. \]  

(9)

If the term \( W_{C3} \) is neglected, the solution of \( H_{C3} \) with the outgoing condition is the well-known C3 approximation, i.e., \( H_{C3} \Psi_{C3} = 0 \), where

\[ H_{C3} = \sum_{j=1}^{3} \frac{1 + \delta_{j,3}}{\xi_j + \eta_j} (H_j^+ + Z_j), \]  

(10)

\[ \Psi_{C3} = \prod_{j=1}^{3} N_j^- F_j^- \]  

(11)

\[ F_j^- = F_1(i \alpha_j; 1; -ik_j \xi_j), \]  

(12)

\[ N_j^- = \exp(-\pi \alpha_j/2) \Gamma(1 - i \alpha_j), \]  

(13)

\( \alpha_j = -Z_j/k_j, j = 1,2,3 \) and \( F_1 \) is the degenerate hypergeometric function. In this work we will concentrate on the outgoing solution (similar structure is found for the incoming solution \( \Psi_{C3}^- \)). For large interparticle distances, \( \Psi_{C3} \) tends to the proper asymptotic solution known as Redmond’s condition:

\[ \lim_{r_j \to \infty} \Psi_{C3} = \prod_{j=1}^{3} E_j^- \text{,} \quad E_j^- = \exp[-i \alpha_j \ln(k_j \xi_j)]. \]  

(14)

The C2 approximation is obtained from \( \Psi_{C3}^- \) by neglecting the e-e interaction to give \( \Psi_{C2} = \prod_{j=1}^{3} N_j^- F_j^- \), which does not satisfy the Redmond’s conditions. Note that if the e-e interaction is switched off, the C2 function is an exact solution of Eq. (4). Therefore, any approximate double continuum wave function should reduce to C2 when \( Z_j = 0 \).

The function \( \Psi_{C3} \) is a solution of the uncorrelated differential operator \( H_{C3} \). Our goal is to find an approximate solution of Eq. (4) valid for large interparticle distances that account for three-body effects beyond the C3 approximation. In generalized parabolic coordinates, the correlation arises in terms containing mixed derivatives. If we want to account for all the crossing derivatives contained in \( W_{C3} \), the two following problems occur:

(i) Today’s computers prohibit solving a six-dimensional differential equation of the type of Eq. (4) in all the variables, i.e., \( \xi_1, \xi_2, \xi_3, \eta_1, \eta_2, \) and \( \eta_3 \). On physical grounds we will neglect the terms containing \( \partial^2 / \partial \xi_j \partial \xi_j \) for the outgoing boundary conditions. Two reasons can be put forward to support this approximation. First, at large distances one can expect that \( \hat{k}_j \) is nearly parallel to \( \hat{r}_j \) and so \( \partial^2 / \partial \xi_j \partial \xi_j \) should vanish. In addition, if we iterate \( \Psi_{C3} \) thus all the terms containing \( \partial \eta_j \) will cancel since it depends only on \( \xi_j \). In conclusion we write the outgoing approximation as

\[ W_{C3} \approx W_{C3} = \sum_{l=1}^{2} (-1)^{l+1} t_j^+ \cdot t_j^+ \frac{\partial^2}{\partial \xi_j \partial \xi_j}. \]  

(15)

If we are interested in the incoming boundary solution instead, we should approximate \( W_{C3} \approx W_{C3}^- \), i.e., we should neglect all the terms containing \( \partial^2 / \partial \xi_j \partial \xi_j \).

(ii) The second problem arises when we try to express the coefficients \( t_j^+ \cdot t_j^+ \) as a function of the parabolic coordinates. This task is quite cumbersome since we have to find the roots of a quartic polynomial as shown in Appendix A. Therefore we are forced to approximate \( t_j^+ \cdot t_j^+ \), having in mind that the solution should have the following properties: for large interparticle distances it goes to Redmond’s solution Eq. (14), it has a regular behavior at total breakup threshold, and the two electrons are treated on equal footing.

A. The use of effective momenta

The wave function \( \Psi_{C3} \) was designed to hold for large interparticle separations \( r_j \to \infty \), but in the semiasymptotic regions, namely,

\[ \Omega_1: \quad r_1/r_2 \to 0, \quad r_2, r_3 \to \infty, \]  

\[ \Omega_2: \quad r_2/r_1 \to 0, \quad r_1, r_3 \to \infty \]  

(16)

\[ \Omega_3: \quad r_3/r_3 \to 0, \quad r_3, r_1, r_2 \to \infty \]  

is not appropriated. In this section, we derive the wave function developed by Alt and Mukhamedzhanov [7] \( \tilde{\Psi}_{AM} \), which is a correlated solution expected to be valid also in all the semiasymptotic regions. To obtain \( \tilde{\Psi}_{AM} \) from our general Eq. (4) with the outgoing approximation Eq. (15), we take the following steps. In the region \( \Omega_1 \) we take into account only the mixed derivative \( \partial^2 / \partial \xi_j \partial \xi_j \) and approximate the coefficient \( t_j^+ \cdot t_j^+ \) by its projection in the direction \( \hat{k}_1 \), i.e.,

\[ t_j^+ \cdot t_j^+ \approx (t_j^+ \cdot \hat{k}_1)(\hat{k}_1 \cdot t_j^+) = \frac{\xi_j}{r_1} \hat{k}_1 \cdot (\hat{k}_3 + \hat{r}_3). \]  

(17)
We look for a solution of the form
\[ \Psi \sim E_2^3 F_{3} r_j ; \xi_j, \]
where \( r_j \) is taken parametrically in \( F \). Further, for \( r_j \to \infty \), we consider
\[ \left[ \frac{\partial}{\partial \xi_j} \frac{\partial}{\partial \xi_j} + \left( \frac{\tilde{k}_j + \tilde{r}_j}{r_3} + \tilde{Z}_j \right) \right] F(r_j ; \xi_j) = 0, \]
and then we arrive at a modified confluent hypergeometric equation in \( \xi_j \):
\[ \left[ \frac{\partial}{\partial \xi_j} \frac{\partial}{\partial \xi_j} + \frac{1}{r_3} \frac{\partial}{\partial \xi_j} + \frac{1}{1 + \tilde{k}_j \cdot \tilde{r}_j} \right] F(r_j ; \xi_j) = 0, \]
where \( k_j' \) is an effective momentum defined by
\[ k_j'(r_j) = k_j + k_j^2 - \frac{1}{r_3} \left( \frac{1 + \tilde{k}_j \cdot \tilde{r}_j}{k_j} \right). \]

Other asymptotic can be covered in a similar way with momenta
\[ k_j'(r_j) = k_j + \frac{1}{2r_3} \left( \frac{1 + \tilde{k}_j \cdot \tilde{r}_j}{k_j} \right) - \frac{1}{2r_3} \left( \frac{1 + \tilde{k}_j \cdot \tilde{r}_j}{k_j} \right). \]

For large interparticle distances, \( k_j' \to k_j \), and the Redmond’s conditions are then satisfied. In this way, we obtain a product of confluent hypergeometric functions as given by Eq. (11)
\[ \Psi_\text{ASYM} \equiv \prod_{j=1}^{3} \Psi_j^r F_j^r, \]
with \( \alpha_j' = -Z_j/k_j' \), instead of \( \alpha_j \) in Eqs. (12) and (13).

It should be noted that the momenta given by Eqs. (21)–(23) are not identical to those found by Alt and Mukhamedzhanov. These authors considered
\[ k_j'_\text{AM}(r_j) = k_j + \frac{\alpha_j}{r_j} \left( \frac{1 + \tilde{k}_j \cdot \tilde{r}_j}{k_j} \right), \]
instead of Eq. (21), and replaced \( r_2 \) by \( (1 + r_2 + r_3)/2 \) to avoid the singularity as \( r_2 \to 0 \). However, as \( r_2 \to \infty \) and \( r_1/r_2 \to 0 \) then
\[ k_j'_\text{AM} r_1 \rightarrow k_j r_1 + O(r_2^2/r_1^2). \]
Therefore \( \Psi_\text{AM} \to \Psi_\text{ASYM} \), i.e., both solutions fall down together in \( \Omega_j \). In an analogous way, it is easy to see that this is also true in each semiasymptotic region. The use of effective momenta was first introduced by Felden [9] in the context of the Vainstein, Pressnyakov, and Sobelman approximation, which can be considered as the forerunner of the C3 one [4].

### B. A numerical test

In this section we explore how effectively the effective momenta introduce correlation between coordinates. The benchmark we pose here is an asymptotic Hamiltonian \( H_\infty \), in which we have assumed \( \eta_1 = \eta_2 = \eta_3 = 0 \), and so \( t_1 \cdot t_3 = 4 \hat{k}_1 \cdot \hat{k}_3 \) to give
\[ H_\infty = \sum_{j=1}^{3} \frac{1}{\xi_j} \left( H_j^r + Z_j \right) + 4 \hat{k}_1 \cdot \hat{k}_3 \frac{\partial^2}{\partial \xi_1 \partial \xi_3} \]
\[ -4 \hat{k}_2 \cdot \hat{k}_3 \frac{\partial^2}{\partial \xi_2 \partial \xi_3}. \]

If we write the series expansion \( \Psi_\infty = \sum_{k,l,m} \hat{C}_k \hat{C}_l \hat{C}_m \), one can obtain the following relation [10]
\[ 0 = \left[ (k+1)^2 f_{k+1,t;1,m-1} + (Z_1 + ik_k) f_{k,t;1,m-1} \right] \]
\[ + \left[ (l+1)^2 f_{k-1;1,t+1,m-1} + (Z_2 + ik_k) f_{k-1;1,t+1,m-1} \right] \]
\[ + 2 \left[ (m+1)^2 f_{k-1;1,t-1,m+1} + (Z_3 + ik_k) f_{k-1;1,t-1,m} \right] \]
\[ + \hat{k}_1 \cdot \hat{k}_3 k m f_{k+1;1,t-1,m} - \hat{k}_2 \cdot \hat{k}_3 \ell m f_{k+1;1,t-1,m}, \]
which cannot be solved for all values of the subscripts. Third, points can be inferred. First, one can easily see that by setting \( \hat{k}_1 \cdot \hat{k}_3 = 0 \), \( \hat{k}_2 \cdot \hat{k}_3 = 0 \), we obviously obtain the C3 function, which satisfies
\[ f_{k+1;1,t,m} = -Z_1 + ik_k k \]
\[ (k+1)^2 f_{k+1;1,t,m}, \]
and similar relations for the other variables. Second, \( \Psi_\infty \) tends to the Redmond’s conditions. And third, the derivative at the origin satisfies Kato’s cusp condition [11]
\[ \left[ \frac{1}{\Psi_\infty} \frac{\partial}{\partial \xi_j} \right]_{\xi_j=0} = -Z_j, \]
which lets us initialize the numerical calculation. The Redmond’s values at large distances and Kato’s derivatives at the origin lead us to a Dirichlet-Neumann mixed-boundary condition problem. The determinant of the coefficients multiplying the second derivative terms is positive, and therefore the differential equation is elliptic, as it is the original Eq. (1).

The numerical solution of Eq. (27) is still quite cumbersome. To reduce the problem we have considered \( \hat{k}_2 \cdot \hat{k}_3 = 0 \) and so \( \hat{k}_1 \cdot \hat{k}_3 = 2 k_1 \). In this case, we write
\[ \Psi_\infty = N_2 F_2 G_{13} (\xi_1, \xi_3), \]
where \( G_{13} \) satisfies
\[ \left[ \frac{2}{\xi_1} (H_1^r + Z_1) + \frac{4}{\xi_3} (H_3^r + Z_3) + \frac{8 k_3}{k_1} \frac{\partial^2}{\partial \xi_1 \partial \xi_3} \right] \]
\[ \times G_{13} (\xi_1, \xi_3) = 0. \]
We have solved Eq. (31) by the finite difference method for \( k_1 = 1, k_3 = 0.4 \), and so \( k_2 = 0.6 \). Results are shown in Fig. 2 where we represent the square modulus of \( G_{13} \) in parabolic coordinates. \( G_{13} \) is compared with the C3 approximation.
$F_{13} = N_1 N_3 F_1 F_3$ and the one having effective momenta $F'_{13} = N'_1 N'_3 F'_1 F'_3$ for $r_2 = 1$. The effective momenta are now

$$k_1' = k_1 + \frac{2\alpha_3}{R} (\hat{k}_3 + \hat{k}_2),$$

$$k_3' = k_3 + \frac{\alpha_1 (\hat{k}_1 + \hat{R}_3)}{1 + \hat{k}_1 \cdot \hat{R}_3} - \frac{\alpha_2 (\hat{k}_2 + \hat{R}_3)}{1 + \hat{k}_2 \cdot \hat{R}_3},$$

where

$$R = 1 + r_1 + r_3,$n

and

$$\mathbf{R}_3 = (r_1 \hat{k}_1 + \hat{k}_2)/2.$$

Some conclusions can be drawn. First, $F'_{13}$ does not differ appreciably from $F_{13}$. Similar conclusions can be inferred also from the article of Jones and Madison [12]; the inclusion of effective momenta does not alter appreciably the electronic distributions. By inspecting the contour plot we can note that the enhancements of $F_{13}$, and even the ones of $F'_{13}$, are situated in a rectangular form, while the ones of $G_{13}$ are slanted. Also the shapes of the enhancement have different forms (similar features have been found also for others values of $k_i$). The effective momenta method does not seem to be a satisfactory solution of the problem. In the next section we introduce an alternative approximation that, we think, may be a good candidate to tackle the double continuum problem.

### III. The $\Phi_2$ Approximation

We look for a wave function with the outgoing boundary condition beyond the C3 approximation by taking into account the mixed derivatives. Let us write the exact expression of the coefficient $t_l^- \cdot t_l^-$:

$$t_l^- \cdot t_l^- = \pm \frac{2 \xi_l}{(\xi_3 + \eta_3)} \pm \frac{4 \xi_3}{(\xi_3 + \eta_3)} \pm \frac{2 r_l^2 + r_7^2 + r_l \cdot r_7}{r_7 r_l} \pm \hat{k}_l \cdot \hat{k}_3 - \hat{k}_l \cdot \left(2 r_l \hat{r}_3 + \frac{\hat{R}_3}{r_3} \cdot (r_l \hat{r}_3)\right),$$

where the upper (lower) sign corresponds to $l = 1$ ($l = 2$). We here will consider just the first two terms

$$t_l^- \cdot t_l^- \equiv \pm \left[\frac{2 \xi_l}{(\xi_3 + \eta_3)} + \frac{4 \xi_3}{(\xi_3 + \eta_3)}\right]$$

$$
\text{to give}
$$

$$W_{C_3} = \pm \frac{2 \xi_3}{(\xi_3 + \eta_3)} \frac{\partial^2}{\partial \xi_1 \partial \xi_3} + \frac{2 \xi_3}{(\xi_3 + \eta_3)} \frac{\partial^2}{\partial \xi_2 \partial \xi_3}$$

$$+ \frac{4 \xi_1}{(\xi_3 + \eta_3)} \frac{\partial^2}{\partial \xi_1 \partial \xi_3} + \frac{4 \xi_2}{(\xi_3 + \eta_3)} \frac{\partial^2}{\partial \xi_2 \partial \xi_3}. $$

FIG. 2. Upper figures display $|G_{13}'|^2$, $|F_{13}'|^2$, and $|F_{13}'|^2$ as a function of $\xi_l = \xi_l(N-1)/\xi_l^{\text{MAX}} = 1.3$ for $k_1 = 1.0$ a.u. and $k_3 = 0.4$ a.u. Lower figures display the corresponding contour plot. The number of nodes $N$ in each direction is $N = 50$ and the maximum value of $\xi_l$ ($\xi_3$) is $\xi_l^{\text{MAX}} = 15$ a.u. ($\xi_3^{\text{MAX}} = 65$ a.u.).
As we shall see, the approximation (36) does not alter the Redmond’s condition. Considering Eqs. (15) and (36) we can reduce Eq. (4) as \(H_{\text{corr}}\Psi_{\text{corr}} = (H_{\text{C3}} + W_{\text{corr}})\Psi_{\text{corr}} = 0\), where

\[
H_{\text{corr}} = \frac{1}{(\xi_1 + \eta_1)} [H_1^{\prime} + Z_1 + \xi_3 \frac{\partial^2}{\partial \xi_1 \partial \xi_3}] + \frac{1}{(\xi_2 + \eta_2)} [H_2^{\prime} + Z_2 + \xi_3 \frac{\partial^2}{\partial \xi_2 \partial \xi_3}] + \frac{2}{(\xi_3 + \eta_3)} [H_3^{\prime} + Z_3 + \xi_1 \frac{\partial^2}{\partial \xi_1 \partial \xi_3} + \xi_2 \frac{\partial^2}{\partial \xi_2 \partial \xi_3}] .
\]

(37)

A closed form of \(\Psi_{\text{corr}}\) is not known to us. The nearest solved case is the fully symmetric system

\[
[H_j^{\prime} + Z_j + \xi_j \frac{\partial^2}{\partial \xi_k \partial \xi_j} + \xi_l \frac{\partial^2}{\partial \xi_l \partial \xi_j}] \Phi = 0 ,
\]

with \(j \neq k \neq l = 1,2,3\) whose solution is the degenerate hypergeometric function of three variables [13] \(\Phi = F_2(i \alpha_1, i \alpha_2, i \alpha_3; 1; -i k_1 \xi_1, -i k_2 \xi_2, -i k_3 \xi_3)\), where

\[
\Phi_2 (\beta, \beta', \beta''; \gamma; x, y, z) = \sum_{km} \frac{(\beta)(\beta')(\beta'')_m}{(\gamma)_k (\gamma)_l} x^k y^l z^m .
\]

(39)

Note that this solution considers a term \(\partial^2 / \partial \xi_j \partial \xi_k\), which is missing in our starting Eq. (37). Consequently, by setting \(Z_3 = 0\), it does not reproduce the C2 approximation, and it should be lied aside. However, Eq. (39) should be considered an appropriate wave function for a three equal-mass system of particles. Next we will find an approximation of Eq. (37) valid for large distances.

To start, we correlate only the variables \(\xi_1\) and \(\xi_3\), i.e., we discard \(\partial^2 / \partial \xi_2 \partial \xi_3\). This restriction allows us to separate Eq. (37) as

\[
\frac{1}{(\xi_1 + \eta_1)} [H_1^{\prime} + Z_1 + \xi_3 \frac{\partial^2}{\partial \xi_1 \partial \xi_3}] \Phi_{13} = 0 ,
\]

(40)

\[
\frac{1}{(\xi_2 + \eta_2)} [H_2^{\prime} + Z_2 + \xi_3 \frac{\partial^2}{\partial \xi_2 \partial \xi_3}] \Phi_{13} = 0 ,
\]

(41)

\[
\frac{2}{(\xi_3 + \eta_3)} [H_3^{\prime} + Z_3 + \xi_1 \frac{\partial^2}{\partial \xi_1 \partial \xi_3} + \xi_2 \frac{\partial^2}{\partial \xi_2 \partial \xi_3}] \Phi_{13} = 0 .
\]

(42)

The solution of this system of equation is \(G_2(\xi_2) G_3(\xi_1, \xi_3)\). Note that it depends only on \(\xi_1, \xi_2,\) and \(\xi_3\) even though we have not imposed any condition on the variables \(\eta_1, \eta_2,\) and \(\eta_3\).

The solution of Eq. (40) is simply a confluent hypergeometric function; \(G_2(\xi_2) = N_2 F_2\). Equations (41) and (42) form a system of partial differential equations studied by Appell and Kampé de Fériet [13]. A solution of this system is a generalization of the confluent hypergeometric function \(\Phi_2\) of two variables, which is expressed as

\[
\Phi_2 (\beta, \beta'; \gamma; x, y, z) = \sum_{km} \frac{(\beta)(\beta')(\beta')_m}{(\gamma)_k (\gamma)_l} x^k y^l z^m .
\]

(43)

Afterwards, the correlated solution of Eqs. (40)–(42) is

\[
\Psi_{13} = N_2 F_2 N_{13}^{\prime} \Phi_{13} ,
\]

(44)

\[
\Phi_{13} = \Phi_2 (i \alpha_1, i \alpha_2, i \alpha_3; 1; -i k_1 \xi_1, -i k_2 \xi_2, -i k_3 \xi_3) ,
\]

(45)

and \(N_{1,m}\) is the factor to resume the Redmond’s conditions (see Appendix B for details)

\[
N_{1,m} = \exp \left( -\pi (\alpha_1 + \alpha_2) / 2 \right) \Gamma (1 - i \alpha_1, i \alpha_2) .
\]

(46)

In similar way, another solution can be obtained accounting \(\partial^2 / \partial \xi_2 \partial \xi_3\) and neglecting \(\partial^2 / \partial \xi_1 \partial \xi_3\):

\[
\Psi_{23} = N_3 F_3 N_{23}^{\prime} \Phi_{23} ,
\]

(47)

Considering the asymptotic behavior of \(\Phi_{13}\) and \(F_j\) shown in Appendix B, it is easy to see that for \(r_i \to \infty\)

\[
H_{\text{corr}} \Psi_{13} = O (r_i^{-2}) ,
\]

(48)

\[
H_{\text{corr}} \Psi_{23} = O (r_i^{-2}) ,
\]

(49)

At this point it is interesting to look for a solution given by

\[
\Psi^- = a N_1 F_1 N_{23}^{\prime} \Phi^- + b N_2 F_2 N_{13}^{\prime} \Phi^- + c \Psi_{C3}^- .
\]

(50)

We found \(a = 1, b = 1\) and \(c = -1\) is the unique solution that (i) satisfies Redmond’s condition as \(r_i \to \infty\), (ii) treats both electrons on equal footing, and (iii) get one order more accuracy as \(r_i \to \infty\), since

\[
H_{\text{corr}} \Psi^- = (r_i^{-3}) .
\]

(51)

We can easily “read” Eq. (51); the first term of the right-hand side contains \(\partial^2 / \partial \xi_2 \partial \xi_3\) to all orders, the second considers \(\partial^2 / \partial \xi_1 \partial \xi_3\), and the third corrects the double counting. Further, if we set \(\alpha_3 = 0\) in Eq. (51), the C2 approximation is recovered, as it is expected. We have used the subscript “F” because Eq. (51) has a structure very similar to the first order Faddeev solution found by Macek [14] and Briggs [15]. In fact, we can derive it considering the Green function of \(H_{\text{C3}}\) instead of the free Green function used in the Faddeev equations [16], and taking \(V_{13} = \pm [2 \xi_1 / (\xi_3 + \eta_3) + 4 \xi_3 (\xi_1 + \eta_1)] \partial^2 / \partial \xi_2 \partial \xi_3\), \(l = 1,2\) as the components of the perturbed potential.

Threshold behavior and normalization factors

The cross section of an ionization process is strongly determined by the behavior at small interparticle separations of the final-state wave function. In the C3 approximation the normalization constant is \(\Psi_{C3} (\xi_1 = 0) = N_{C3} = N_{1} N_{2} N_{3}^{-1}\), and it is well known that the use of \(\Psi_{C3}\) leads to cross
sections that underestimate experimental data by orders of magnitude [6] in the threshold of double photoionization, i.e., in the Wannier region [19]. The origin of this failure arises from the overestimation of the e-e repulsion given by the Coulomb factor \( N_2 \). It decreases exponentially for small decreasing excess energy. Figure 3 shows the square modulus of the \( N_2 \) normalization factor for \( k_1 = 1 \) as a function of \( k_2 \) so that \( k_2 \) is parallel to \( k_1 \).

In this work, we present a correlated wave function for the three-body Coulomb problem valid for large interparticle distances. Unlike other works [7,8] where the correlation is introduced parametrically, here we consider the contribution of the mixed derivatives. Let us resume the three steps to obtain \( \Psi_F^- \): (i) from the full Hamiltonian, we take the outgoing approximation, i.e., \( W_{C3} \approx W_{C3}^0 \) as in Eq. (15); (ii) we further approximate \( W_{C3} \approx W_{cor} \) as in Eq. (36) by considering the first two terms of Eq. (34) as stated in Eq. (35); and (iii) finally, we approximate the solution of Eq. (37) by using the first order of the Faddeev expansion as in Eq. (51).

In this way, we found a genuine many-variable wave function \( \Psi_F^- \), which treats the electrons on equal footing and it seems to correct the overestimation of the interelectronic repulsion of \( \Psi_{C3}^0 \). Other systems can be treated in similar way, e.g., the problem of an electron in the field of two nuclei [17].

It is important to remark that the solution \( \Psi_F^- \) is not valid in the semiasymptotic regions. If we want such a solution, we could introduce effective momenta [7] (as shown in Sec. II) or effective charges [8] (using the coordinate system of the reference).

Further work is being carried out to compute transition matrices. A numerical calculation using the hypergeometric function of two variables \( \Phi_2 \) presents several difficulties due to the complexity of the problem.

### ACKNOWLEDGMENTS

We would like to acknowledge M. Kornberg for helpful discussions and J. Etcheverry for considerable helpful advice on numerical methods.

### APPENDIX A: CHANGE OF COORDINATES

In Eq. (3) we posed the generalized parabolic transformation \((r_1, r_2) \rightarrow (\xi_1, \xi_2, \xi_3, \eta_1, \eta_2, \eta_3)\); in this appendix we look for the inverse transformation. We write \( r_j = (x_j, y_j, z_j), l = 1, 2, 3, k_j = (k_{jx}, k_{jy}, k_{jz}), j = 1, 2, 3, \) and for convenience we choose \( x_1 \) parallel to \( k_i \) (i.e., \( k_{1y} = k_{1z} = 0 \)). Introducing the variables

\[
\sigma_1 = (\xi_1 - \eta_1)/2, \quad \sigma_2 = (\xi_1 + \eta_1)^2/4, \quad (A1)
\]

\[
\sigma_3 = (\xi_2 - \eta_2)/2, \quad \sigma_4 = (\xi_2 + \eta_2)^2/4, \quad (A2)
\]

\[
\sigma_5 = (\xi_3 - \eta_3)/2, \quad \sigma_6 = (\xi_3 + \eta_3)^2/4, \quad (A3)
\]

\[
\sigma_0 = 1/2(\sigma_2 + \sigma_4 - \sigma_6), \quad (A4)
\]

\[
\rho_1 = k_{2x}\sigma_3 + k_{3x}\sigma_5 - k_{3y}\sigma_1, \quad \rho_2 = k_{2x}\sigma_3 - k_{3y}\sigma_1, \quad (A5)
\]

\[
\tau_1 = k_{3x}/k_{3y}, \quad \tau_2 = k_{2x}/k_{2y}, \quad (A6)
\]
we find the value of $x_2$ is the solution of the following quartic equation

$$0 = [\sigma_2 - \sigma_1^2 - (\rho_1 + \tau_1 x_2)^2][\sigma_2 - x_2^2 - (\rho_2 + \tau_2 x_2)^2]$$

$$- [\sigma_2 - x_2 - (\rho_1 + \tau_1 x_2)(\rho_2 + \tau_2 x_2)].$$  \hfill (A7)

The inverse transformation is then $x_1 = \sigma_1$, and the rest of the variables are related to $x_2$ through the relations

$$y_1 = \rho_1 + \tau_1 x_2,$$  \hfill (A8)

$$z_1 = [\sigma_2 - \sigma_1^2 - (\rho_1 + \tau_1 x_2)^2]^{1/2},$$  \hfill (A9)

$$z_2 = [\sigma_4 - x_2^2 - (\rho_2 + \tau_2 x_2)^2]^{1/2}. \hfill (A10)$$

This procedure to obtain the inverse transformation is quite tedious due to the discrimination of the different roots. Next, we will study some particular cases.

1. The Crothers's condition

This is the case when $k_l$ is parallel to $r_l$, for $l = 1, 2$ [18]. In terms of the generalized parabolic coordinates, it can be expressed as $\eta_1 = \eta_2 = 0$, thus

$$x_2 = \frac{\xi_1^2 + \xi_2^2 - (\xi_3 + \eta_3)^2}{4 \xi_1}. \hfill (A11)$$

The cancellation of $\eta_{1,2}$ constrains the values of $\xi_3$ and $\eta_3$ to

$$\left[ \frac{\xi_3}{\eta_3} \right] = \left[ \frac{(\xi_1^2 + \xi_2^2 - 2 \xi_1 \xi_2 k_1 \cdot k_2)^{1/2}}{2} \right] \left[ \frac{+}{-} \right] N, \hfill (A12)$$

$$N = \xi_1 N_1 + \xi_2 N_2, \quad N_l = \frac{k_l^2 - k_1 \cdot k_2}{4 k_1 k_2}, \hfill (A13)$$

and $l = 1, 2$. It is concluded then that the wave function depends on only two variables: $\xi_1$ and $\xi_2$.

2. Peterkop's condition

This is the case when the three position vectors $r_j$ are parallel to $k_j$, for $j = 1, 2, 3$, and so $\eta_1 = \eta_2 = \eta_3 = 0$ [20]. Thus,

$$x_2 = \frac{\xi_1^2 + \xi_2^2 - \xi_3^2}{4 \xi_1}. \hfill (A14)$$

Therefore only one parameter is the independent variable and the following constraint is observed:

$$t = \frac{\xi_1}{\left[1 - (k_2 \cdot k_3)^2\right]^{1/2}} = \frac{\xi_2}{\left[1 - (k_1 \cdot k_3)^2\right]^{1/2}}$$

$$= \frac{\xi_3}{\left[1 - (k_1 \cdot k_2)^2\right]^{1/2}}, \hfill (A15)$$

where $t$ is a parameter that can be seen as the time.

3. Wannier’s condition

This is the case when the electrons recede from each other; thus, $r_1 = -r_2$ and so $x_3 = -\sigma_1$ [19]. Under these circumstances only three variables are independent, for example $\xi_1, \xi_2$, and $\eta_1$, and the rest of the coordinates are constrained to hold

$$\eta_2 = \xi_1 + \eta_1 - \xi_2,$$  \hfill (A16)

$$\xi_3 = \xi_1 + \eta_1 + \frac{k_1}{2 k_3} (\xi_1 - \eta_1) + \frac{k_2}{2 k_3} (2 \xi_2 - \xi_1 - \eta_1),$$

$$\eta_3 = \xi_1 + \eta_1 - \frac{k_1}{2 k_3} (\xi_1 - \eta_1) - \frac{k_2}{2 k_3} (2 \xi_2 - \xi_1 - \eta_1) \hfill (A17)$$

If, in addition, we consider Crother’s condition, i.e., $k_l$ parallel to $r_l$, for $l = 1, 2$ (or equivalently $\eta_1 = \eta_2 = 0$), then we find $\eta_3 = 0, \xi_2 = \xi_1$, and $\xi_3 = 2 \xi_1$.

APPENDIX B: ASYMPTOTIC BEHAVIOR

In order to show the asymptotic behavior of the function $\Phi_2(\beta, \beta'; \gamma, x, y)$ as $x \to \infty$ and $y \to \infty$, we start by expressing $\Phi_2$ in its integral form

$$\Phi_2(\beta, \beta'; \gamma, x, y) = \frac{\Gamma(\gamma)}{\Gamma(\beta') \Gamma(\beta) \Gamma(\gamma - \beta - \beta')} \times \int \int du dv \exp(ux + vy) u^{\beta - 1} v^{\beta' - 1}$$

$$\times (1 - u - v)^{\gamma - \beta - \beta' - 1}, \hfill (B1)$$

where the integral is taken over the triangular region $u \geq 0, v \geq 0$, and $1 - u - v \geq 0$. Using the integral form of the confluent hypergeometric function [21]

$$\int_0^1 F_1(\nu, \mu + v, \lambda u) = \frac{\Gamma(\mu + \nu)}{\Gamma(\mu) \Gamma(\nu) u^{1 - \mu - v}}$$

$$\times \int_0^u ds s^{\nu - 1} (1 - s)^{\mu - 1} e^{\lambda s}, \hfill (B2)$$

we can reduce Eq. (B1) to a single integral:

$$\Phi_2(\beta, \beta'; \gamma, x, y) = \frac{\Gamma(\gamma)}{\Gamma(\beta) \Gamma(\gamma - \beta)} \int_0^1 du \exp(ux) u^{\beta - 1}$$

$$\times (1 - u)^{\gamma - \beta - 1} F_1(\beta', \gamma - \beta, (1 - u) y). \hfill (B3)$$

Since the limit as $|z| \to \infty$ of $F_1(a, b, z)$ is

$$F_1(a, b, z) \to \frac{\Gamma(b)}{\Gamma(b - a)} e^{-iaz} a^{-b}, \hfill (B4)$$
\( e = \text{sgn}[\text{Im}(z)] \), then we find

\[
\Phi_2(\beta, \beta'; y, x, y) \rightarrow \frac{\Gamma(\gamma)}{\Gamma(\gamma - \beta - \beta')} \exp\left(-i \varepsilon \pi \beta\right) \\
\times \exp(-i \varepsilon \pi \beta') x^{-\beta} y^{-\beta'}
\]

as \( x, y \rightarrow \infty \) \hspace{1cm} (B5)

with \( \varepsilon_x = \text{sgn}[\text{Im}(x)] \), and \( \varepsilon_y = \text{sgn}[\text{Im}(y)] \). Therefore, the asymptotic behavior of \( \Psi_{13} \) in Eq. (44) is given by

\[
\Phi_2(\alpha_1, \alpha_3, 1, -ik_1 \xi_1, -ik_3 \xi_3) \rightarrow \frac{1}{N_{1,3}} E_1^\gamma E_3^\Gamma
\]

(B6)

with

\[
N_{1,3} = \exp(-\pi \alpha_1/2) \exp(-\pi \alpha_3/2) \Gamma(1 - i \alpha_1 - i \alpha_3)
\]

(B7)

and similar expressions for any other pair of correlated particles.
